

An Open-Source Reaction Wheel System for Oregon's First Satellite

Jeremy A. Louke Erin S. Schmidt Calvin J. Young

OreSat

- **Mission:** STEM outreach by sending live video space-to-ground to tracking stations built and operated by Oregon high schools
- Ground stations will be built using 3D printers, COTS WiFi adapter cards, and existing augmented reality cellphone apps that track satellites
- Downlink via 2.4 GHz 802.11b "DxWiFi" on helical with 1 W amplifier and approximately 15 dBi gain. Need to "point-and-stare" at ground stations with **5-10° of pointing at 1 deg/s of slew**
- Can not satisfy slew and pointing accuracy requirements with magnetorquers so we're using a **reaction wheel** based system

μ -gravity Controls Testing

- Bode analysis of cube dynamics in "space-like" free-fall environment
- Portland State University's Dryden Drop Tower facility can access a 1×10^{-5} to 10^{-6} -g environment for 2.1 s
- Cube damps roll following a random (25% duty cycle PWM) perturbing impulse

Open Source

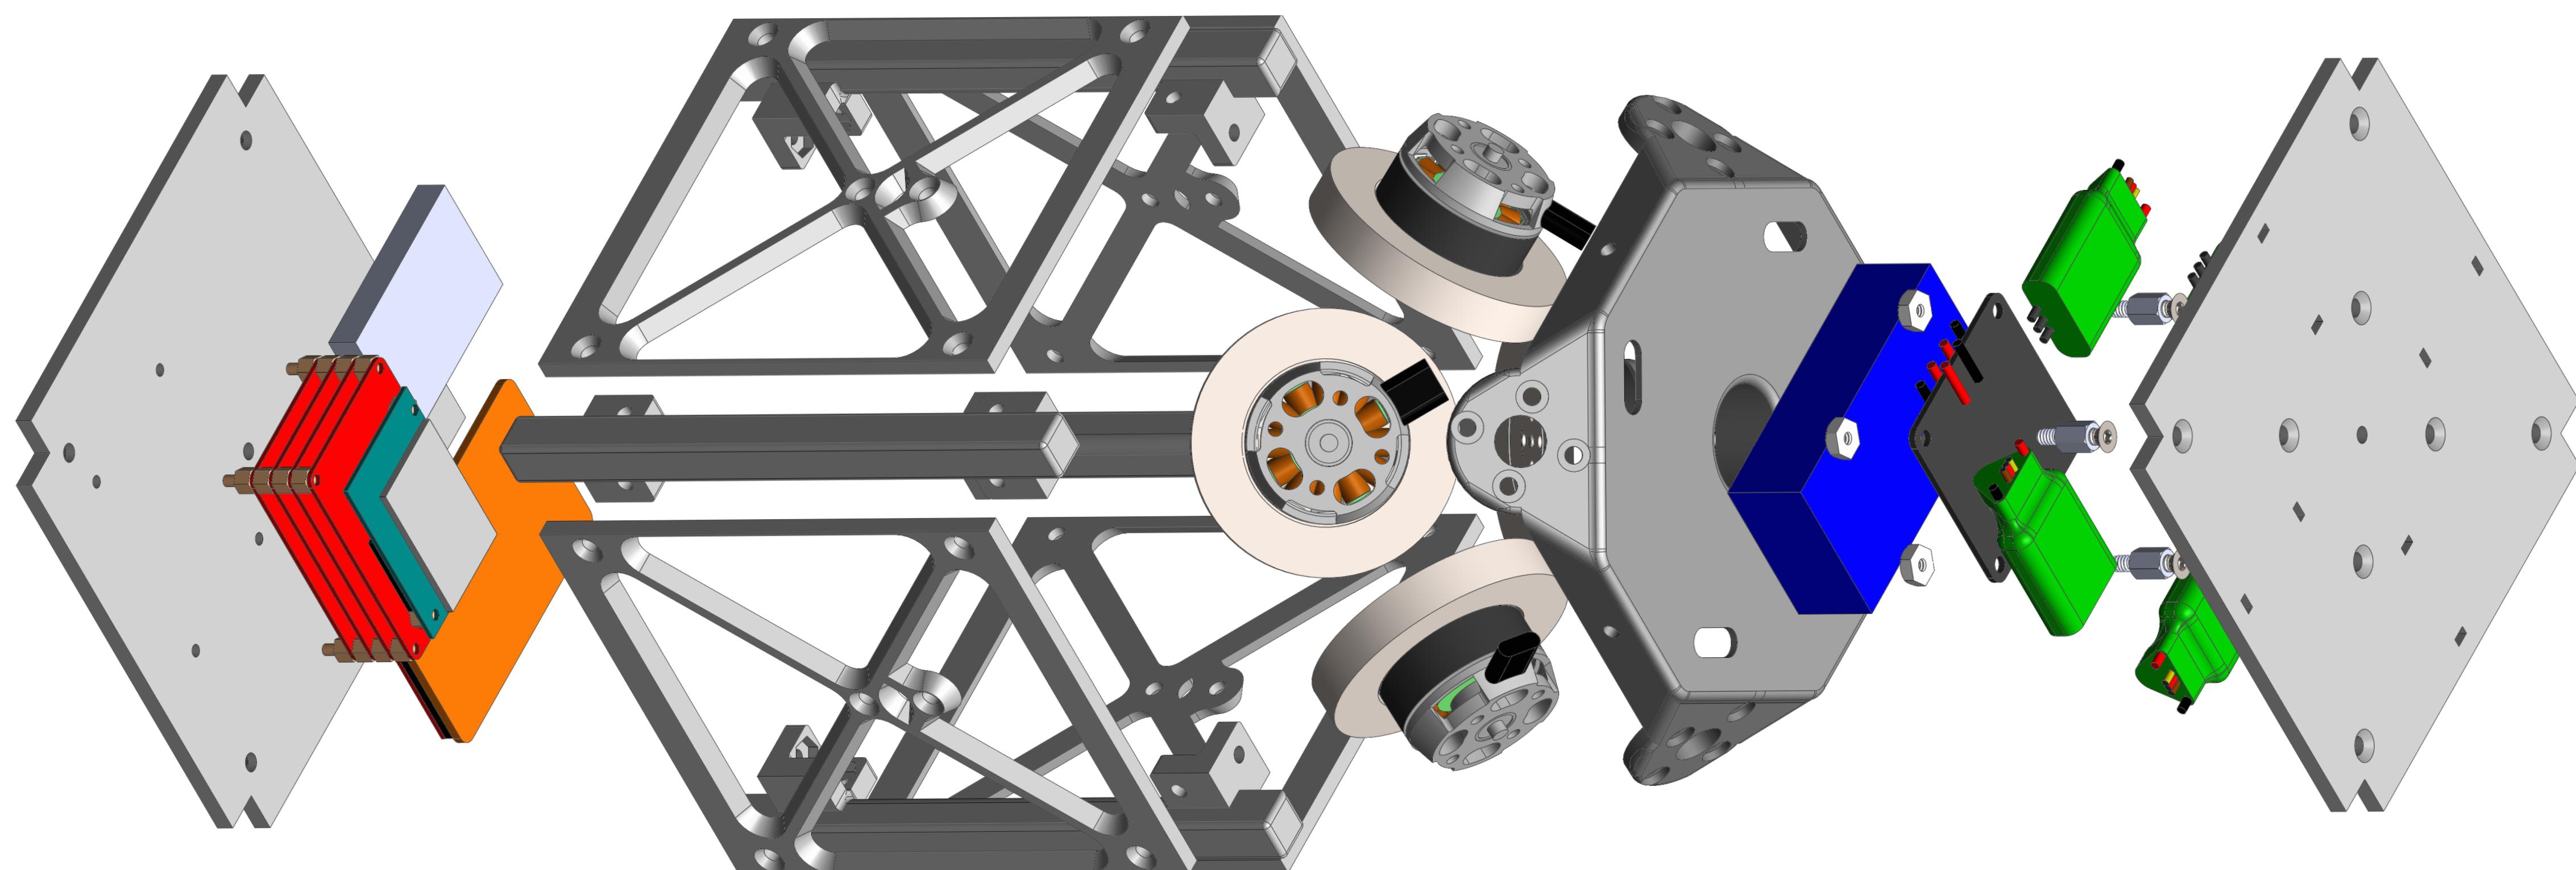

- Project deliverables freely and publicly available under a GNU GPL v2 license
- <https://github.com/oresat>

Further Work

- Need more drop-tests: complete Bode diagram to improve dynamical model, further controller design iterations
- State determination with sensor fusion via Kalman filtering suntracker, magnetometer, and gyroscopes

Rapid Prototyping

- Designed for rapid iteration
- Uses FDM 3D prints for the main structure
- COTS components include: DC Brushless hobby motors, LiPo battery packs, Intel Edison microcontroller, and Sparkfun "blocks"
- Controller code written in Python, for readability and ease of sharing

Figure: The reaction wheel subsystem test cube.

Controls Development

- The controller for the reaction wheel system is a simple PID loop
- The microcontroller receives feedback from a 9-DoF IMU over analog-in, and sends signals via GPIO to the DC motors.
- The top-level controller design procedure was as follows:
 1. Determine the transfer functions from dynamics analysis of free body diagrams of the system
 2. Create simulation in GNU Octave
 3. Design the controller using iterative testing (with comparisons to the model) and classical Bode techniques
- The forces acting on the cube are the torques created by the motors T_i^0 , damping effects $b_1\dot{\theta}_{cube}$, and spring effects $G_1\theta_{cube}$. Summing the moments around the center of gravity gives the following equation (for the x-axis):

$$M_0^+ = I_{x,cube}\ddot{\theta}_{x,cube} = T_{Ax}^0 + T_{Bx}^0 - T_{Cx}^0 - T_{Dx}^0 + T_x^0 - \dot{\theta}_{x,cube} - G_x\theta_{x,cube}.$$

- By setting the system to Standard Equilibrium Position (at SEP the input perturbations are set to zero), considering only a single input, substituting the torque-inertia relation, and taking the Laplace transform we have the transfer function of the cube:

$$G_A(s) = \frac{\theta_{x,cube}(s)}{\theta_A(s)} = \frac{s^2}{\frac{I_{x,cube}}{\sin(45^\circ)I_{rw}}s^2 + \frac{b_x}{\sin(45^\circ)I_{rw}}s + \frac{G_x}{\sin(45^\circ)I_{rw}}}.$$
